Question:

$$x dy - y dx = \sqrt{x^2 + y^2} dx \quad (0.1)$$

Theoretical solution:

$$\frac{dy}{dx} = \frac{y}{x} + \sqrt{1 + \frac{y^2}{x^2}} \quad (0.2)$$

$$\text{Let } \frac{y}{x} = t \quad (0.3)$$

$$\frac{dy}{dx} = x \frac{dt}{dx} + t \quad (0.4)$$

Substitute equations (0.2) and (0.3) in (0.1)

$$x \frac{dt}{dx} = \sqrt{1 + t^2} \quad (0.5)$$

$$\frac{1}{\sqrt{1 + t^2}} dt = \frac{1}{x} dx \quad (0.6)$$

Integrate on both sides to obtain the solution

$$\int \frac{1}{\sqrt{1 + t^2}} dt = \int \frac{1}{x} dx \quad (0.7)$$

$$\ln(t + \sqrt{1 + t^2}) = \ln x \quad (0.8)$$

$$t + \sqrt{1 + t^2} = x \quad (0.9)$$

Substitute $t = \frac{y}{x}$

$$y + \sqrt{x^2 + y^2} = x^2 \quad (0.10)$$

$$y = \frac{x^2 - 1}{2} \quad (0.11)$$

Method of finite differences : The finite difference method is rooted in the fundamental concept of approximating derivatives using finite differences.

The derivative of $y(x)$ can be approximated as

$$\frac{dy}{dx} = \frac{y(x+h) - y(x)}{h} \quad (0.12)$$

$$y(x+h) = y(x) + h \left(\frac{dy}{dx} \right) \quad (0.13)$$

Where h is a small value very close to zero.

Substitute (0.1) in (0.12)

$$y(x+h) = y(x) + h \left(\frac{y}{x} + \sqrt{1 + \frac{y^2}{x^2}} \right) \quad (0.14)$$

Let (x_0, y_0) be a point on the curve.

Let some $x_1 = x_0 + h$. Then,

$$y_1 = y_0 + h \left(\frac{y}{x} + \sqrt{1 + \frac{y^2}{x^2}} \right) \quad (0.15)$$

On Generalizing the above equation, we have

$$x_{n+1} = x_n + h \quad (0.16)$$

$$y_{n+1} = y_n + h \left(\frac{y_n}{x_n} + \sqrt{1 + \frac{y_n^2}{x_n^2}} \right) \quad (0.17)$$

This curve is generated by applying the finite difference method to the given problem and taking the values of $x_0 = 1, y_0 = 0$ and $h = 0.001$ and running the iterations for 500 times
